                                        6 *       NOTE: This is a copy of the CLCL Unaligned Buffers Test
                                        7 *             modified to test the CLCLE instruction.
                                        8 *             James Wekel August 2022
                                        9 ********************************************************************
                                       10 *
                                       11 *  This program tests proper functioning of the CLCLE instruction's
                                       12 *  optimization logic (specifically, the "mem_cmp" function that the
                                       13 *  CLCLE instruction makes use of) to ensure the location of the in-
                                       14 *  equality is properly reported.
                                       15 *
                                       16 *  Depending on the alignment of the two operands being compared, if
                                       17 *  the length of the compare is large enough that it would cause the
                                       18 *  comparison to cross a page boundary for both operands and the in-
                                       19 *  equality occurs at an offset past the distance each operand is
                                       20 *  from its respective page boundary added together, then the address
                                       21 *  of the inequality that CLCLEreturns would be off by the shorter
                                       22 *  of the two distances.
                                       23 *
                                       24 *  For example, if the operand addresses were X'123456' and X'456789'
                                       25 *  (and the page size was X'800') and the inequality was at (or past)
                                       26 *  X'123877', then CLCLE would incorrectly report the address of the
                                       27 *  inequality as being at address X'123877' - X'77' = X'123800':
                                       28 *
                                       29 *  X'123456' is X'3AA' bytes from the end of its page boundary.
                                       30 *  X'456789' is X'77'  bytes from the end of its page boundary.
                                       31 *  The true inequality is at X'123877' (X'123456' + X'77' + X'3AA').
                                       32 *
                                       33 *  The optimization logic would perform three separate compares: the
                                       34 *  first starting at X'123456' for a length of X'77'. The second one
                                       35 *  at address X'1234CD' (X'123456' + X'77') for a length of X'3AA',
                                       36 *  and the third and final compare at address X'123877' (X'123456' +
                                       37 *  X'77' + X'3AA') for a length of at least one byte.
                                       38 *
                                       39 *  Due to a bug in the original optimization logic however the length
                                       40 *  of the first compare would not be added to the calculated offset of
                                       41 *  where the inequality was located at.  That is to say, the offset of
                                       42 *  the inequality would be calculated as operand-1 + X'3AA' instead of
                                       43 *  operand-1 + X'77' + X'3AA'.  The X'77' offset would get erroneously
                                       44 *  lost, thereby causing the location of the inequality to be reported
                                       45 *  X'77' bytes BEFORE where the actual inequality was actually located
                                       46 *  at! (Oops!)
                                       47 *
                                       48 *  The bug has since been fixed of course but to ensure such does not
                                       49 *  occur again, this standalone runtest test performs a series of CLCL
                                       50 *  comparisons whose parameters are such that they end up tripping the
                                       51 *  bug as described. Thank you to Dave Kreiss for reporting the bug.
                                       52 *
                                       53 ********************************************************************
